For our project, we are building an application that will allow households to maintain a centralized shopping list, based on the separate personal lists created by individuals of the household.

E/R Diagram

Descriptions

Through our application, any individual can create an *Account* with a unique

accountName and a *password* for the respective household. *Users* are then created within the

Account, representing the different individuals within that household.

Each of the *Users* will have a unique *name*. Every one of the *Users* also has exactly one

PersonalList which is identified by a unique *userID*.

The entity *PersonalList* also contains the attribute *itemName*, the *quantity* requested, the

priority of each item, and the attribute *notes*. This is representative of the individual shopping

list, held by each owner of a household.

By default, the *Account* has exactly one *PurchaseHistory*, and each *PurchaseHistory*

belongs to exactly one *Account*. Attributes of *PurchasedHistory* include the *buyer* of the item,

the attribute *itemName*, the *date* of purchase, the *price* of each item, the *quantity* of the items

bought, and the attribute *belongsTo*, which represents to whom's list the *Item* belongs to.
